- A. Exercise 2.4b.
- B. Exercise 2.4c.
- C. Exercise 2.4f.
- D. Exercise 2.6b.

Here is our CFG from class for fully parenthesized algebraic expressions:

```
<expr> ::= <var> | <num> | (<expr><op><expr>)
<var> ::= <char> | <char><var>
<char> ::= a | ... | z | A | ... | Z | _
<num> ::= <dig> | <dig><num>
<dig> ::= 0 | ... | 9
<op> ::= + | * | ^ | - | /
```

E. Based on the CFG above, draw the parse tree for the expression

((3 * (4 / temp)) - ((x + 50) * (rate ^ pow)))

Mimic the textbook's examples in Section 2.1, with variables labeling branch nodes and terminals labeling leaf nodes. For example, the root node of your parse tree will be labeled **<expr>**. Do not take shortcuts; draw the entire tree.

F. Prove that every regular language is context-free, by showing that any regular expression can be converted into a context-free grammar that describes the same language. Hint: Use structural induction, as we did in converting regular expressions to NFAs.
